

# DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

Discover. Learn. Empower.

## Experiment 1

Student Name: Devendra Singh

UID: 23BCS12483

Branch: BE-CSE

Section: Group: KRG-3A

Semester: 6

Date of performance: 08-01-2026

Subject name: System Design

Subject code: 23CSH-314

### **AIM:**

To design, implement, and evaluate a simple URL redirection system that converts long URLs into short URLs, and to measure system performance (latency and throughput) under varying request loads.

### **OBJECTIVE:**

1. To understand the working of a URL shortening service.
2. To design REST APIs for URL creation and redirection.
3. To identify suitable database and server choices.
4. To analyze different short URL generation techniques.
5. To understand scalability challenges and their solutions.

### **PROBLEM STATEMENT:**

Design a URL Shortener system that converts long URLs into short URLs and redirects users from short URLs to original long URLs with low latency, high availability, and scalability.

### **1. Requirements:-**

#### **A. Functional Requirements:-**

1. Generate a short URL from a long URL.
2. Support custom URLs (optional).
3. Support URL expiration (default and custom).
4. Redirect short URL to the original long URL.
5. User registration and login using REST APIs.

# DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

## B. Non-Functional Requirements:-

1. Low Latency: URL creation and redirection < 20ms
2. Scalability:
  - 100M daily active users
  - 1B shortened URLs
3. Availability: System should be available 24×7.
4. Uniqueness: Each short URL must be unique.
5. CAP Theorem:
  - Availability > Consistency
  - Eventual Consistency model.

## System Entities

1. User
2. Long URL
3. Short URL

## 2. API Design:-

1. Create Short URL Endpoint: POST /v1/url

### Request Body:

```
{  
  "longURL": "string",  
  "customURL": "string (optional)",  
  "expirationDate": "date"  
}
```

### Response:

```
{  
  "shortURL": "https://short.ly/2bi"
```

# DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

}

## 2. Redirect Short URL

Endpoint: GET /v1/url/{shortURL}

Action: Redirects to original long URL.

## 3. User APIs

- POST /v1/register
- POST /v1/login

## 3. Database Design:-

Table T1 – User Metadata

Column	Description
user_id	Primary Key
name	User Name
email	Unique
password	Encrypted
created_at	Timestamp

Table T2 – URL Table

# DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

Column	Description
id	Primary Key
shortURL	Unique
longURL	Original URL
customURL	Optional
expirationDate	Expiry Time
user_id	Foreign Key

## 4. High Level Design (HLD) Components:-

1. Client (Browser / App)
2. Server (Business Logic)
3. Database (Storage)

Flow:

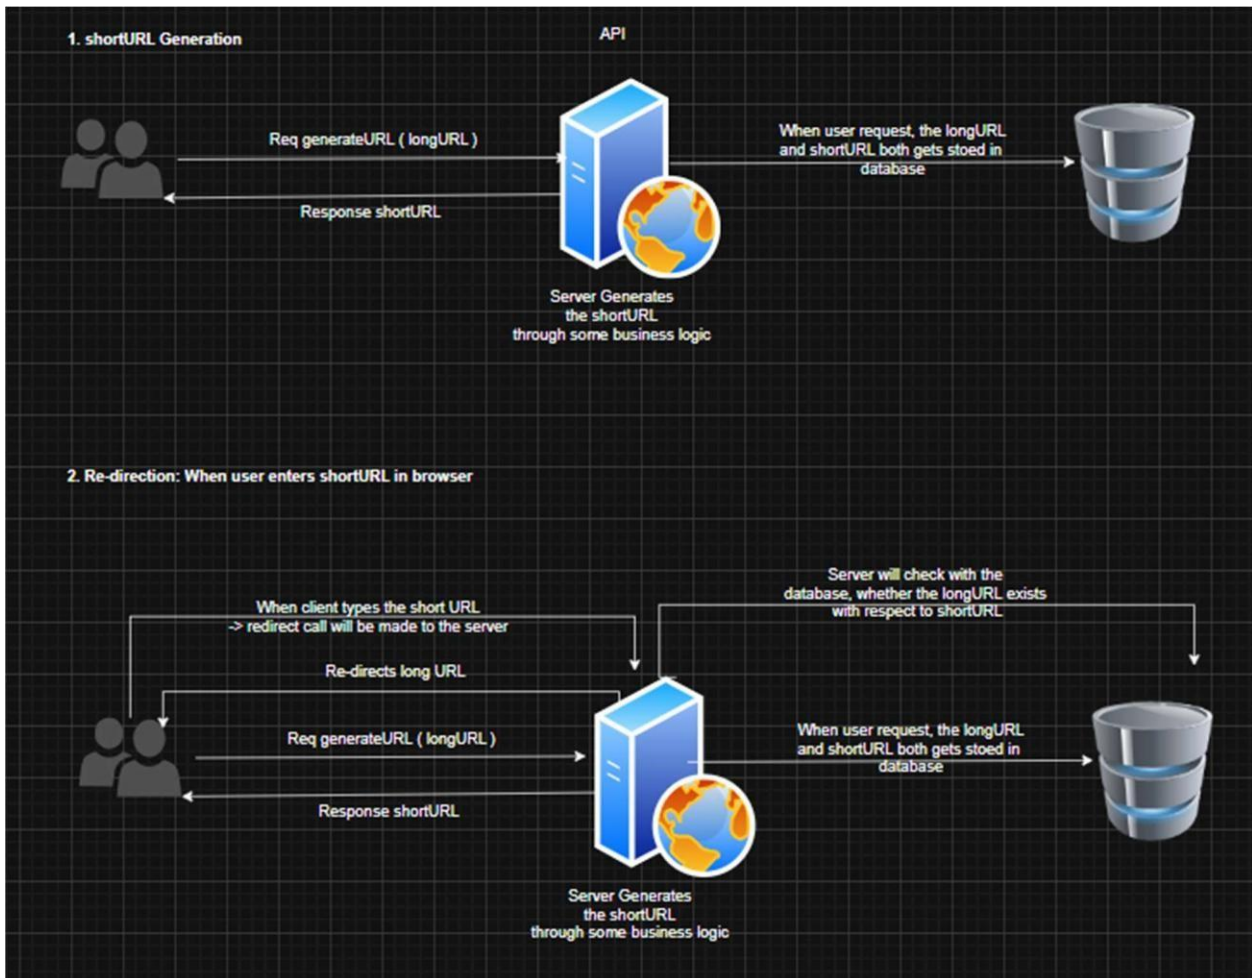

Client → Server → Database → Server → Client

### 1. Workflow

1. Short URL Generation 1. Client sends long URL request.
2. Server generates short URL.
3. Server stores long URL + short URL in database.
4. Server responds with short URL.

### 2. Redirection

1. Client enters short URL.
2. Server validates short URL from database.
3. Server redirects to original long URL.

## 5. Low Level Design (LLD):-

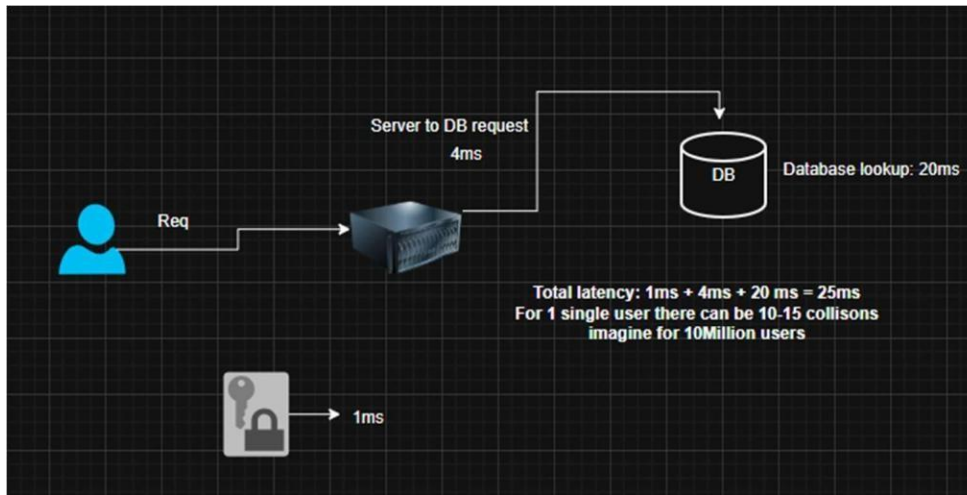

### Approach 01: Hashing (Encryption)

Method: shortURL = encrypt(longURL)

Algorithms: MD5, SHA-1, Base64

Problems:

1. Long hash length (not short).
  2. High collision probability.
  3. Multiple DB lookups.
  4. High latency at scale.
- Not suitable for large-scale systems

## Approach 02: Counter-Based Approach (Recommended)

Logic:

1. Generate a global counter value.
2. Convert counter to Base62.
3. Use Base62 value as short URL.

Example:

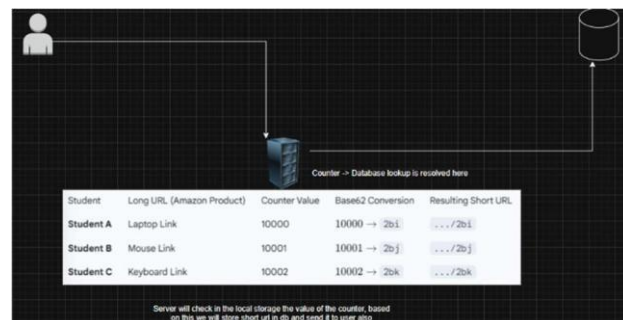

Counter = 10000

Base62 = 2bi

Short URL = short.ly/2bi

Advantages

- No collision
- Fast generation
- Predictable length

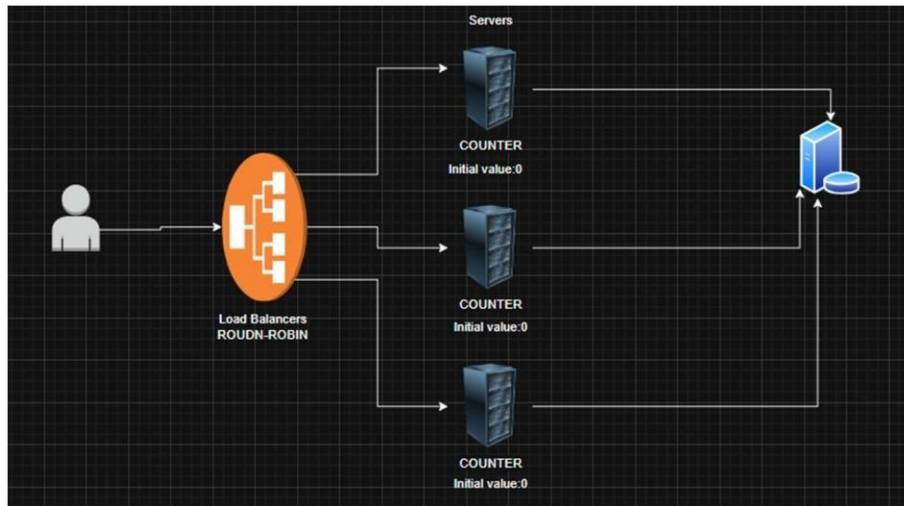

## Scaling Challenges & Solutions

Problem 1: Monolithic Server

- Cannot handle 100M users

Solution: Horizontal Scaling (Multiple Servers)

## Problem 2: Distributed Counter Conflict

- Multiple servers may generate same counter.

Solution:

Use Global Counter in Cache (Redis) with atomic increment.

Type of Database Used

Recommended

- NoSQL (Key-Value Store)

# DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

- Redis (Cache)
- DynamoDB / Cassandra (Persistent)

Reason:

- Fast read/write
- High availability
- Easy horizontal scaling

Type of Server

- Stateless REST API Server □ Deployed behind Load Balancer
- Performs:
  - URL validation
  - Counter fetch
  - Base62 conversion
  - DB read/write

## Steps to Do Experiment

Step 1: Set Up the Project

```
bash
```

```
mkdir url-shortener && cd url-shortener
```

```
python -m venv venv
```

```
source venv/bin/activate # On Windows: venv\Scripts\activate
```

```
pip install flask
```

Step 2: Write the URL Shortener Code

Create a file app.py:

# DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

```
python
```

```
from flask import Flask, redirect, request, jsonify
```

```
import hashlib
```

```
import time
```

```
import threading
```

```
from collections import defaultdict
```

```
app = Flask(__name__)
```

```
url_map = {}
```

```
metrics = {'total_requests': 0, 'latencies': []}
```

```
def generate_short_code(long_url):
```

```
    return hashlib.md5(long_url.encode()).hexdigest()[:8]
```

```
@app.route('/shorten', methods=['POST'])
```

```
def shorten():
```

```
    start_time = time.time()
```

```
    long_url = request.json.get('url')
```

```
    short_code = generate_short_code(long_url)
```

```
    url_map[short_code] = long_url
```

```
    latency = time.time() - start_time
```

```
    metrics['latencies'].append(latency)
```

```
    metrics['total_requests'] += 1
```

```
    return jsonify({'short_url': f'http://localhost:5000/{short_code}'})
```

# DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

```
@app.route('/<short_code>')
def redirect_url(short_code):
    start_time = time.time()
    long_url = url_map.get(short_code)
    if long_url:
        latency = time.time() - start_time
        metrics['latencies'].append(latency)
        metrics['total_requests'] += 1
        return redirect(long_url, code=302)
    return 'URL not found', 404

@app.route('/metrics')
def get_metrics():
    if metrics['latencies']:
        avg_latency = sum(metrics['latencies']) / len(metrics['latencies'])
        throughput = metrics['total_requests'] / (time.time() - app_start_time)
    else:
        avg_latency = throughput = 0
    return jsonify({
        'avg_latency_sec': avg_latency,
        'throughput_req_per_sec': throughput,
        'total_requests': metrics['total_requests']
    })

def load_test(concurrent_users=10):
```

# DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

```
import requests
```

```
def worker():
```

```
    requests.post('http://localhost:5000/shorten', json={'url':  
'https://www.example.com/page?q=test'})
```

```
    threads = [threading.Thread(target=worker) for _ in range(concurrent_users)]
```

```
    for t in threads: t.start()
```

```
    for t in threads: t.join()
```

```
if __name__ == '__main__':
```

```
    app_start_time = time.time()
```

```
    app.run(debug=True)
```

Step 3: Run the Server

```
bash
```

```
python app.py
```

Step 4: Test the Endpoints

Use Postman or curl to test:

POST to <http://localhost:5000/shorten> with JSON {"url": "<https://www.example.com>"}

GET to [http://localhost:5000/<short\\_code>](http://localhost:5000/<short_code>) to redirect

GET to <http://localhost:5000/metrics> to see performance data

Step 5: Perform Load Testing

Modify the `load_test()` function to simulate different loads (10, 50, 100 users).

# DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

Run load tests and record metrics from /metrics endpoint.

## Step 6: Record Observations

Create a table to compare latency and throughput for different loads.

### Sample Input

```
json
{
  "url": "https://www.google.com/search?q=system+design+course"
}
```

### Sample Output

After shortening:

```
json
{
  "short_url": "http://localhost:5000/a1b2c3d4"
}
```

Metrics after 100 requests with 10 concurrent users:

```
json
{
  "avg_latency_sec": 0.012,
  "throughput_req_per_sec": 45.7,
  "total_requests": 100
}
```

**RESULT:-**

# DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING

A scalable and highly available URL Shortener System was successfully designed using counter-based Base62 encoding, REST APIs, NoSQL database, and distributed architecture principles.

## **CONCLUSION:-**

The counter-based approach with centralized atomic counters provides the most efficient, scalable, and collision-free solution for a URL Shortener system handling millions of users with low latency.
